## ABSTRACT

The aim of this paper is twofold. Firstly, we study the determinants of growth among a wide set of potential variables for the Spanish provinces (NUTS3). We include several types of private, public and human capital in the group of growth factors. Moreover, we analyse whether Spanish provinces have converged in economic terms in the past decades. The second objective is to overcome the problems of model uncertainty and robustness of estimated parameters in growth regressions using cross-section and panel data techniques. For this purpose, we use a Bayesian Model Averaging (BMA) approach. The Bayesian methodology constructs parameter estimates as a weighted average of linear regression estimates for every possible combination of included variables. The weight of each regression estimates is given by the posterior probability of each model. This technique allows us to obtain parameter estimates that are robust to model specification.

**JEL classification:** O4, H5, C11.

**Key Words:** Growth, Convergence, Public Investment, Bayesian Model Averaging .

## 1. INTRODUCTION

The search for the determinants of economic growth is one of the main puzzles in economics. Many studies, from both a theoretical and an empirical point of view, have focused on finding the main factors that can explain observed growth rates.

From a theoretical point of view, many efforts have been devoted to understand the complex economic processes behind growth. Neoclassical growth models à la Solow (1956) identified some of the factors that can play an important role on growth rates. For instance, private investment, population growth, exogenous technological progress and the initial level of income per capita are pointed out as main determinants of the rate of economic growth.

From a different standpoint, the endogenous growth literature<sup>1</sup> gave an important impulse to single-equation macroeconomic models for cross-section of economies (either countries or regions). These models indicate as a potential source of growth many factors such as political institutions, economic policy factors, knowledge accumulation or institutional indicators. As a result, theoretical models and empirical evidence give more than 60 variables significantly correlated with growth (Sala-i-Martin, 1997).

Faced with such a variety of sources of growth, the aim of this paper is two-fold. Firstly, using both cross-section and panel data techniques we study the determinants of growth among a wide set of potential variables for the Spanish provinces (NUTS3) for the period 1965-1995. We include several types of private, public and human capital in the group of growth factors. Moreover, we analyse whether Spanish provinces have converged in economic terms in the past decades. The second objective is to overcome the problems of model uncertainty and robustness of estimated parameters in growth regressions using cross-section and panel data techniques. For this purpose, we use a Bayesian Model Averaging (BMA, hereafter) approach. The Bayesian methodology constructs parameter estimates as a weighted average of linear regression estimates for every possible subset of potential regressors. The weight of each regression estimates is given by the posterior probability of each model. This technique allows us to obtain parameter estimates that are robust to model specification.

The paper is organised as follows. Section 2 briefly revises some of the main contributions to the empirics of growth, and highlights some of its drawbacks. Section 3 presents the methodology used in this paper. Section 4 describes the variables and data used to perform the empirical estimations. Section 5 presents the main results obtained. Finally, section 6 concludes.

---

<sup>1</sup> The endogenous growth theories were "initially motivated by the apparent inability of earlier neoclassical models to explain some important features of cross-country income and growth data" de la Fuente (1997).

## 2. EMPIRICAL GROWTH REGRESSIONS

Theoretical models have been accompanied by an ever-growing empirical economic growth literature. "Empirical issues have played a key role in the recent literature on economic growth" (de la Fuente, 1997).

Cross-section regressions were initially proposed by Kormendi and Meguire (1985), and Barro (1991). The basic methodology consists in regressing growth rates of per capita output<sup>2</sup> against a set of possible explanatory variables. However, the problem faced by empirical growth economists is that growth theories are not explicit enough about what variables belong in the "true regression" (Doppelhofer, Miller and Sala-i-Martin, 2000)<sup>3</sup>.

The inclusion of other variables, apart from those directly derived from theoretical models, has been "justified" because of the presence of the "level of technology",  $A$ , in the standard production function; it can be interpreted in many ways, and not only as the level of technology present at the economy. Therefore, many factors not directly embodied in a neoclassical production function may affect the aggregate level of output. These other factors can range from weather conditions to attitudes towards work; all of them could be potentially included as sources of growth making the decision of which variables to include in an empirical estimation very difficult. Moreover, the presence of these variables, which usually are specific to each of the economies analysed and sometimes are unobservable, raised the problem of the existence of a non-zero correlation between these economy-specific effects and the explanatory variables of the model, implying the possibility of obtaining biased estimated coefficients. To solve this, and other possible problems present in the econometric estimation of growth regressions, Knight, Loayza and Villanueva (1993), and Islam (1995) proposed to use panel data techniques in this framework. Panel data techniques allow us to capture the unobserved individual effects in each of the economies analysed.

### 2.1. Human and Public Capital

Among the numerous variables included in growth regressions two factors have been the subject of much of the theoretical and empirical growth literature: human and public capital.

The literature on theoretical growth models suggests alternative ways of understanding the effects of human capital. Mankiw, Romer and Weil (1992) presented an "extended" neoclassical growth model with human and public capital.

---

<sup>2</sup> Normally measured with Gross Domestic Product (GDP) or Gross Value Added (GVA).

<sup>3</sup> For an extensive review on cross-country growth regressions, see de la Fuente (1997), Durlauf and Quah (1999) or Temple (1999).

Human capital is introduced directly in the production function as another input of production. This suggests that investment in human capital is a determinant of growth, and should therefore be included as an explanatory variable. In contrast, Nelson and Phelps (1966) argued that an economy with a higher level of human capital can innovate, implement and adopt new technologies more efficiently, and therefore, obtain a higher growth rate. Models developed with this approach introduce the stock of human capital as a determinant of the growth rate of the economy<sup>4</sup>. Hence, growth equations derived from these two alternative approaches include two different types of human capital variables: investment or stock. Our empirical estimations take into account these different approaches by introducing different types of human capital variables.

The theoretical literature that includes public services (either as flow or stock variable) is wide. Since the seminal work of Barro (1990), many models have taken into account the flow of services provided by the government. For instance, Futagami *et al.* (1993) construct a model with public capital and transitional dynamics. Glomm and Ravikumar (1994), and Fisher and Turnovsky (1998) explicitly allowed public capital to be subject to congestion<sup>5</sup>. Moreover, the empirical estimations performed by Aschauer (1989) and Munnell (1990) on the effect of public capital on private sector productivity opened a new stream of research that aimed to assess the relevance of public capital in the economy. Many studies were performed and different, and sometimes contradictory, evidence was found<sup>6</sup>. The impact of public investment on growth is subject to controversy because of the trade off between the positive effects of public capital as an input of production versus the potentially negative effects derived from the taxes necessary to finance public capital.

Finally, we also include variables with information about the sectoral structure of the economies analysed in our estimations. Serrano (1999) and de la Fuente and Freire (2000) provide theoretical grounds to the inclusion of sectoral structure variables in growth regressions, and study the effect of these variables in the Spanish case. Section 4 describes the data and variables used in our estimates.

## 2.2. The Spanish Case

Growth regressions have been also applied to the regional (provincial) case. In the regional framework, the number of possible variables that can be used as growth determinants is smaller than in the case of regressions analysing coun-

---

<sup>4</sup> For more details, see Gorostiaga (1999).

<sup>5</sup> Bajo-Rubio (2000) introduces various types of public spending in a growth framework, showing their effects on the growth rate of the economy.

<sup>6</sup> For a review on the empirical estimation of the effect of public capital, see Gramlich (1994) or Button (1998).

tries. However, if we include, as we do in this study, measures of different types of human and public capital the number of variables raises substantially.

Most of the studies in the growth regression literature have used "convergence equations". Estimation of convergence equations, directly derived from the neoclassical growth model, allows not only to study significance of the variables initially included in the model, but it also explores the controversial issue of economic convergence across economies<sup>7</sup>.

Pioneering works were Dolado *et al.* (1994) where the convergence issue was analysed for the Spanish provinces, and Raymond and García-Greciano (1994) who studied regional convergence in Spain. These works were followed by other regional studies such as de la Fuente (1994, 2002), García-Greciano *et al.* (1995), Mas *et al.* (1994, 1995, 1998), Cuadrado *et al.* (1999), Gorostiaga (1999), Salas (1999), Raymond and García-Greciano (1999), among others. Using different specifications and econometric tools, convergence among Spanish regions has been a common result in these works.

Recently, Gorostiaga (1999) and González-Páramo and Martínez (2002) present an extended neoclassical growth model with human and public capital, based on Mankiw, Romer and Weil (1992), and tested the existence of convergence for the Spanish regions<sup>8</sup>. They found evidence supporting the conditional convergence hypothesis, however, human and public capital seem to have little or no effect on the growth rate of the economy. However, their results are potentially determined by the econometric specification chosen. Hence, more robust empirical estimations are desirable.

### 2.3. Robustness of Growth Results

The multiplicity of relationships established between many factors and growth bring a wide range of specifications to be empirically tested. As Durlauf and Quah (1999) highlighted, empirical economist are inclined to follow theory rather loosely, and simply "try" variables determining economic growth (Sala-i-Martin, 1997). Econometric problems such as endogeneity of regressors, non-linearity, non-stationarity, model specification, and multicollinearity are likely to appear<sup>9</sup>.

<sup>7</sup> For a good review of the convergence hypothesis, its drawbacks and estimation issues see Quah (1993, 1996).

<sup>8</sup> Gorostiaga (1999) performs estimations for Spanish regions (17) for the period 1969-1991, and González-Páramo and Mart[ $\square$ ]nez (2002) for the period 1965-1995. Both articles use panel data techniques with instrumental variables (GMM estimator proposed by Arellano and Bond, 1991).

<sup>9</sup> Many other problems can affect growth regressions such as aggregation problems, economic interpretation of the coefficients or measurement problems in poor economies (see, Durlauf, 1996).

Levine and Renelt (1992) proposed a variant of Leamer's (1983) extreme-bounds analysis (EBA, hereafter) to test the robustness of coefficient estimates to alterations in the conditioning set of information. They study a wide variety of economic policy, political and institutional indicators; however, they fix a certain number of variables to be included in all the possible combinations of the others variables. These factors always included by Levine and Renelt (1992) were the initial level of income, the investment rate, the secondary school enrolment and the rate of population growth. They conclude that very few regressors are significant when the EBA tests are used. However, Sala-i-Martin (1997), Durlauf and Quah (1999) and Dopperlhofer, Miller and Sala-i-Martin (2000) pointed out how the EBA test is too strong for any variable to pass: "if there is one regression for which the sign of the coefficient changes, or becomes insignificant, then the variable is labelled as fragile".

Sala-i-Martin (1997) moved away from the EBA-type tests and proposed to look at the entire distribution of the estimated coefficients: the main idea is to assign levels of confidence to each variable by computing the cumulative density function for each estimated coefficient. He performed the estimations for 62 variables, keeping 3 always fixed in all regressions<sup>10</sup> and combining the rest 58 in sets of three. He found that 22 variables appeared to be significant<sup>11</sup>.

Recently, Florax, Groot and Heijungs (2002) highlight the serious limitations of the sensitivity analysis conducted by Levine and Renelt (1992) and Sala-i-Martin (1997). While these "robustness" tests have focused merely on sign and significance of the estimated parameters, fixing a number of variables that always appear in the regression, the procedure of keeping key variables constant has important effects on the results (affecting the estimated sizes of the parameters).

Bayesian techniques have been also applied to the empirical growth regression approach. Studies by Fernández, Ley and Steel (2000) and Dopperlhofer, Miller and Sala-i-Martin (2000) use Bayesian approaches to adequately tackle the problem of model uncertainty in growth regressions. This is the methodology used in this paper, and it is explained in next section.

### 3. METHODOLOGY

This section is devoted to briefly describe the methodology employed to perform our estimations. The main idea is to "admit that we do not know which model is "true" and, instead, attach probabilities to different models", Dopperl-

---

<sup>10</sup> The initial values of income, life expectancy and primary school enrollment.

<sup>11</sup> Among these significant variables, we can find openness, different types of investment, types of economic organization, market distortions, and different regional, political and religious variables.

hofer, Miller and Sala-i-Martin (2000). The methodology presented allows us to avoid selecting “a priori” a subset of regressors, as in other “robustness” studies; therefore, we obtain the estimated coefficients as an average over models, using the corresponding posterior model probabilities as weights.

### 3.1. Bayesian Model Averaging

We consider a linear regression with a constant term  $\alpha$  and  $k$  potential regressors  $z_1, z_2, \dots, z_k$ . This gives rise to  $2^k$  possible models, depending on which subset of regressors is included in the model. In the cross-section case, we represent each model  $M_j$  by:

$$y_i = \alpha + Z_i^j \beta_j + \varepsilon_i \quad i = 1, \dots, N$$

where  $Z_i^j$  denotes a subset of  $k_j$  regressors, and  $\beta_j$  is a vector containing the corresponding slope parameters. Note that in model  $M_j$ , the rest of slope parameters not contained in  $\beta_j$  are assumed to be zero. Furthermore, we assume that in every model the error terms are normally and independently distributed, with variance equal to  $\sigma$ . Although normality is not necessary for consistency, it guarantees good finite sample properties (see, Fernández, Ley, and Steel, 2000).

In the panel data case, model  $M_j$  is of the type:

$$y_{it} = \alpha_1 d_1 + \alpha_2 d_2 + \dots + \alpha_N d_N + Z_{it}^j \beta_j + \varepsilon_{it} \quad i = 1, \dots, N \quad t = 1, \dots, T$$

where the coefficients  $(\alpha_1, \alpha_2, \dots, \alpha_N)$  are the individual effects and  $d_1, d_2, \dots, d_N$  are  $N$  dummy variables. As before, we assume that the error terms are normally and independently distributed, with variance equal to  $\sigma$ . Since we assume the individual effects enter in all models, the number of possible models is also in the panel data case equal to  $2^k$ .

Rather than selecting just one model, the Bayesian approach suggests to average the results from different model specifications. Bayesian Model Averaging (BMA) follows directly from the application of Bayes’ theorem and implies mixing over models using the posterior model probabilities as weights. Min and Zellner (1993) show that such mixing over models minimises expected predictive squared error loss, provided the set of models under consideration is exhaustive.

The probability of each model is determined by the predictive likelihood,  $\pi(y)$ , which is the normalising constant in the denominator of Bayes’ theorem. Let  $\pi(\theta)$  be the prior distribution for the set of parameters  $\theta$ . The parameter vector  $\theta$  includes slope parameters and variance parameters ( $\theta = \beta, \sigma$ ). In the case of fixed effects panel data models,  $\theta$  would also include the individual effects ( $\theta = \beta, \sigma, \alpha_1, \alpha_2, \dots, \alpha_N$ ).

If we denote the likelihood function by  $\pi(y|\theta)$ , the posterior density is given by Bayes' theorem:

$$\pi(\theta|y) = \frac{\pi(\theta)\pi(y|\theta)}{\pi(y)},$$

where the normalising constant

$$\pi(y) = \int \pi(\theta)\pi(y|\theta)d\theta,$$

is the predictive likelihood, and is used for model comparison. This constant determines the probability that the specified model is correct.

The probabilities for alternative models are evaluated with the predictive likelihood. Given  $m$  possible models  $\{M_i\}$  and prior probabilities for each model  $\pi(M_i)$ , the posterior probability for model  $M_i$  is

$$\pi(M_i|y) = \frac{\pi(M_i)\pi(y|M_i)}{\sum_j \pi(M_j)\pi(y|M_j)}.$$

The ratio of the probabilities of two models is known as Bayes' factor. Although the posterior probability depends on the number of models  $m$ , which is determined a priori, the ratio of the probabilities of two different models does not depend on  $m$ . In the case of equal prior probabilities for each model, the Bayes' factor is equal to:

$$B_{ij} = \frac{\pi(y|M_i)}{\pi(y|M_j)}.$$

For instance, a Bayes' factor equal to 2 would mean that model  $M_i$  is 2 times more likely than model  $M_j$ , i.e. the probability that model  $M_i$  is the true model is 2 times the probability that  $M_j$  is the true model. If there were no more models under consideration, the probability of model  $M_i$  would be 0.66, and the probability of model  $M_j$  0.33.

The posterior probabilities for each model lead to a procedure to deal with uncertainty about the appropriate model to use. The posterior density for  $\theta$  takes into account the different possible specifications,

$$\pi(\theta|y) = \sum_{j=1}^m \pi(\theta|y, M_j) \pi(M_j|y).$$

The posterior mean for  $\theta$  is a weighted average of the posterior means in each model,

$$E(\theta|y) = \sum_{j=1}^m E(\theta|y, M_j) \pi(M_j|y), \quad (1)$$

where the weights are the posterior probabilities of each model. An expression for the posterior variance of  $\theta$  is given by Leamer (1978) and is equal to:

$$\text{Var}(\theta | y) = \sum_{j=1}^m \text{Var}(\theta | y, M_j) \pi(M_j | y) + \sum_{j=1}^m (\mathbb{E}(\theta | y, M_j) - \mathbb{E}(\theta | y))^2 \pi(M_j | y). \quad (2)$$

From this expression, it is clear that the posterior variance of  $\theta$  incorporates both the variances in individual models as well as the variability in estimates of  $\theta$  across different specifications, hence taking into account model uncertainty.

### 3.2. Prior density

Fernández *et al.* (2001) conduct a Monte Carlo study to assess the properties of different prior densities. We use the prior that they recommend for the cross-section case. Let  $Z_j$  be the  $N \times k_j$  matrix which contains the  $k_j$  regressors which enter in model  $M_j$ . For the constant term and variance parameter the prior is improper and non informative:

$$\pi(\alpha) \propto 1 \quad \pi(\sigma) \propto \sigma^{-1}$$

The prior for the slope parameters  $\beta_j$  in model  $M_j$  is a normal density with zero mean and covariance matrix equal to:

$$\sigma^2 (g_0 Z_j^T Z_j)^{-1},$$

with

$$g_0 = \min\left\{\frac{1}{N}, \frac{1}{k^2}\right\}.$$

The expression for the Bayes' factor with this prior specification is given in Fernández *et al.* (2001) in expression (2.16), in page 392.

In the panel data case, let  $\bar{Z}_j = (Z_j, d_1, d_2, \dots, d_N)$  be a  $NT \times (k_j + N)$  matrix containing  $k_j$  regressors and the  $N$  dummy variables. The prior for  $(\beta_j, \alpha_1, \dots, \alpha_N)$  under model  $M_j$  is a normal density with zero mean and covariance matrix equal to:

$$\sigma^2 (g_0 (\bar{Z}_j)^T (\bar{Z}_j))^{-1},$$

with

$$g_0 = \min\left\{\frac{1}{(NT)}, \frac{1}{(k + N)^2}\right\}.$$

The prior for the variance parameter is the same as in the cross-section case:

$$\pi(\sigma) \propto \sigma^{-1}.$$

The Bayes' factor with this prior specification can be found in Fernández et al (2001), in expression (2.12) with  $m_1 = 0$ .

Fernández *et al.* (2001) show that these prior specifications lead to Bayes' factors, which are consistent. Hence, as the sample size increases, the probability of the correct model tends to one, and therefore the probabilities of wrong models tend to zero. In addition, this property holds even if the error term is not normally distributed.

### 3.3. Implementation

When the number of parameters is large, obtaining the posterior mean and variance given in expressions (1) and (2) implies an extremely large number of calculations. This is because the number of models under consideration increases dramatically with the number of potential regressors, at the rate  $2^k$ . In order to reduce the computation time, we follow the algorithm proposed by Madigan and York (1995).

The algorithm constructs a Markov Chain defined over the set of models under consideration. The probability that the Markov Chain visits each of the models is equal to their posterior probabilities. Hence, the posterior probability of each model can be approximated by the relative frequencies of visits in the Markov Chain. Posterior means and variances can be then calculated using these probabilities in expressions (1) and (2).

The Markov Chain is constructed as follows. Let  $M^n$  denote the model visited by the Markov Chain in period  $n$ . The model in period  $(n+1)$  is determined in the following way:

1. Generate a new candidate model, say  $M_j$ , from a Uniform distribution over the subset of models consisting in model  $M^n$  and all models containing either one regressor more or one regressor less than  $M^n$ .
2. Fix  $M^{n+1}$  equal to  $M_j$  with probability  $\gamma = \min\{1, B_{js}\}$ , where  $B_{js}$  is the Bayes' factor. And fix  $M^{n+1}$  equal to  $M^n$  with probability  $1 - \gamma$ .

## 4. VARIABLES AND DATA

In the study of the Spanish provinces, the number of specific characteristics that could influence the growth rates for each province is reduced. Many of the variables used in cross-country growth regressions are not appropriate when analysing the Spanish case. However, the consideration of different types of human and public capital, and a measure of sectoral structure increases the number of potential determinants of growth.

The empirical estimations in this study are performed with both cross-section and panel data techniques for the period 1965-1995. Our main interest is the analysis of long-run determinants of provincial growth rates, however, we perform also short-run estimations for both the cross-section and panel data models (results are presented in the appendix).

Each model (cross-section or panel data) is estimated in two forms; first, we include the aggregates of private and public capital; second, these variables are introduced divided in various types (for definitions see below).

The dependent variable in our estimates is the *Growth Rate of per capita Gross Domestic Product* (GDP). Provincial GDP series are expressed at 1986 constant prices, with biannual observations, and were obtained from Fundación BBV<sup>12</sup> (FBBV, hereafter). Population series are obtained from Instituto Nacional de Estadística (INE) and cover the relevant data span. These series have been used also to compute the *Population Growth* rate, another variable introduced in our regressions.

#### 4.1. Private Investment

We make use of the ratio of private investment to provincial GDP. Private investment series are expressed at 1986 constant prices, and are obtained from FBBV. Moreover, we split this variable in five types of private investment: *Agriculture, Energy, Industry, Construction and Services*. *Total Private Investment* is the sum of these five types, and therefore, excludes private residential investment.

#### 4.2. Public Investment

This variable reflects the ratio of public investment (undertaken by all public administrations) to provincial GDP. Public investment is expressed at 1986 constant prices and is obtained from FBBV. Following the empirical literature, we only consider productive public investment (*Total Public Investment*), or in other words, investment in *Highways and Roads, Hydraulic infrastructures, Urban Structures, Ports and Airports*.

#### 4.3. Human Capital

There is not a unique measure of human capital. Different proxies have been used in the empirical literature. First, we use proxies of human capital as proposed by Mankiw, Romer and Weil (1992), that have been extensively used in the empirical literature: the share of working age population with a certain level of studies

---

<sup>12</sup> Fundación BBV has a regional database on the internet: <http://bancoreg.fbbv.es>. Alternatively, data can be obtained from Instituto Valenciano de Investigaciones Económicas (IVIE). Information on construction and exact definitions of variables can be found at Mas *et al.* (1996).

over the overall level of workers in each province. Data is obtained from the human capital series elaborated by the IVIE; additional information can be obtained from Mas *et al.* (1995) and Serrano (1999). We have used four measures (proxies) of human capital:  $H1$  is the share of working age population with no studies (illiteracy),  $H2$  is the share for workers with primary school,  $H3$  with secondary studies, and finally  $H5$  is the share of working age population with high university degree<sup>13</sup>.

Some doubts have been raised, in the empirical literature, about the adequacy of these variables as a proxy of human capital (or investment in human capital). However, we use them in our estimations because we want to evaluate if these variables should be included in a growth regression or not, or in other words, if they are robust as growth determinants. Moreover, we have constructed an additional measure of human capital ( $H_i$ ).

The procedure to construct the human capital variable builds on Mincer's (1974) function of returns on education, which relates the salary obtained by a worker with her/his level of education. From Mincer's specification, we can obtain a measure of human capital as follows (see Jones, 1997):

$$H_i = e^{\gamma S_i} L_i,$$

where  $H_i$  is the calculated human capital stock measure,  $\gamma$  are the average returns on schooling,  $L_i$  is the overall level of workers in province  $i$ , and finally  $S_i$  is the average years of schooling of the working population in each province<sup>14</sup>. Furthermore,  $S_i$  is calculated as follows:

$$S_i = \sum_j n_j \frac{W_{ij}}{L_i},$$

where  $j$  represents the level of instruction attained,  $n_j$  is the number of years necessary to obtain the  $j^{\text{th}}$  level of education,  $W_{ij}$  are the number of workers of province  $i$  with a level of education  $j$ .

Following the criteria of IVIE we have considered five levels of education ( $j$ ), each one with its corresponding number of years to obtain that level ( $n_j$ ): illiteracy (0), primary school (3,5), secondary school (11), university (16), and high degrees in university or college graduates (17).

Finally, we have used the estimations of Alba-Ramírez and San Segundo (1995) of returns to schooling in Spain. The authors calculate the Mincerian specification of earnings equation in Spain, obtaining a value of 8.36% ( $\gamma=0.0836$ ). This overall rate of return value is very close to the value obtained by Psacharopoulos (1994) for Europe (8.5%).

---

<sup>13</sup> We have omitted the forth classification provided by IVIE, which should correspond with  $H4$  (workers with university), to avoid econometric problems in the empirical estimation.

<sup>14</sup> Time subscripts have been omitted for clarity.

#### 4.4. Sectoral Structure

The variables used to study the effects of the sectoral structure on the growth rates are the provincial *Share in Agriculture* and *Share in Industry* with respect total Gross Value Added (GVA) in the province. We have omitted the services share of GVA to avoid problems of multicollinearity.

#### 4.5. Other variables

The use of panel data techniques allows us to introduce “fixed effects” in growth regressions, or in other words, to account for all those intrinsic characteristics to each province. However, in the cross-section estimates we have introduced other variables that can account for (some) of these individual (to each province) effects. Therefore, we have introduced the logarithm of the *Initial Level of per capita GDP* to analyse the convergence across Spanish provinces, and the initial share of working population with primary and secondary school. We have called these variables *Initial Primary Enrollment* and *Initial Secondary Enrollment* respectively. A variable that indicates the *Area* of each province ( $Km^2$ ) has been introduced to study if there are scale effects that can affect growth rates (see Escot and Galindo, 2000), as well as a dummy variable that indicates the *Localization* of each province (north versus south)<sup>15</sup>. Finally, a variable of *Fertility*, the provincial gross birth rate, has been introduced also in the cross-section estimates.

### 5. RESULTS

This section is devoted to present the main results obtained in this study. The algorithm presented in section 3.3 was run with 50000 iterations, and the first 3000 were not used to compute the posterior means and probabilities. Repeating the analysis with a different initial model yielded very similar results, indicating that the number of iterations was sufficient.

Table 1a presents the results for the long run cross-sectional estimates with aggregate private and public capital, while table 1b presents the estimations when private and public investment are disaggregated. Similarly, table 2a and 2b present the results for the panel data estimates<sup>16</sup>. Each table contains four columns: name of the variables, posterior Bayesian probability of inclusion, poste-

<sup>15</sup> This variable was inspired on the work by Dolado et al. (1994). They estimate growth regressions for different groups of provinces.

<sup>16</sup> Similarly, in appendix we report the corresponding results for short-run estimates, cross-section and panel data, in tables 1c, 1d, 2c and 2e.

rior mean of slope coefficient ( $\beta$ 's), and posterior standard deviation for each parameter. The results are ordered by posterior probability of inclusion.

Long run cross-section estimates (tables 1a and 1b) suggests that the initial level of GDP is an important growth determinant, with a probability of inclusion of 0.97 and 0.71. The negative sign supports the hypothesis of conditional convergence across Spanish provinces for the whole period analysed (1965-1995). However, the short run estimates conducted with cross-sectional techniques (tables 1c and 1d in the appendix) show how this variable has probability of inclusion around 0.5 but with a positive coefficient, indicating the possibility of persistence of income disparities in the short run<sup>17</sup>.

<sup>17</sup> It is difficult to find significant short-run determinants of growth. However, our aim in conducting these cross-section regressions was to estimate the posterior probability of inclusion and the sign of the parameter for the initial level of income: recent empirical studies on convergence indicate the likely existence of persistence of income inequalities and divergence patterns in the short run for Spanish provinces, see for instance Lamo (2000) or Leonida and Montolio (2001).

Total private investment has a high posterior probability of 0.91, and a positive coefficient of around 1%. When we analyse the different components of private capital (table 1b), we find that private investment in agriculture, construction and services have posterior probabilities of inclusion between 25% and 35%.

Human capital variables show a lower probability of inclusion, ranging from 0.16 to 0.23. Our measure of human capital ( $H_i$ ) seems to have a positive effect, but it gets posterior probabilities of inclusion of 0.23 and 0.10.  $H_2$  seems to be marginally correlated with growth rates, with probabilities of inclusion around 0.18, and a small and positive posterior mean.

When public investment is introduced as the total amount of productive spending, it has a very low probability of inclusion 0.06. The disaggregation of this variable causes two types of public investment to have larger probabilities (public investment in ports and airports), with negative but very small estimated coefficients.

Finally, the sectoral structure variables obtain a probability of 0.18 of inclusion in the cross-sectional estimates. The rest of the variables introduced seem to have no robust effects on cross-section growth regressions for the Spanish provinces.

Cross-section estimates can have econometrics problems; some of them can be solved by adopting panel data techniques. The fact that we introduce a fixed effect for each province accounts for all individual and unobservable effects, allowing them to be correlated with the explanatory variables. Tables 2a and 2b present long run growth regressions using panel data in the BMA approach. Surprisingly, human capital variables ( $H_2$  and  $H_3$ ) obtain the highest probability of inclusion (1) and both have negative estimates. The agricultural share of GVA also has probability of inclusion equal to one and a positive coefficient. Interestingly, public investment has a 0.93 probability of inclusion and a positive and reasonable elasticity of 1.3%, similar to the one obtained for private investment.

In the disaggregated results (table 2b), there are two types of private investment with probability of inclusion equal to 1: private investment in industry and construction, with elasticities of 2.3% and 3%, respectively.<sup>18</sup> Population growth has posterior probability of inclusion equal to one and shows the expected theoretical sign (negative).

Public investment in roads gets a high probability (0.90) and a positive elasticity of 0.5%, while public investment in urban structures seems to have a possibly negative role on growth rates. The other types of public investment get small probabilities of inclusion.

---

<sup>18</sup> González-Páramo and Martínez (2002) obtain similar results for total private investment.

In contrast with the cross-section results, two types of human capital have large probabilities of inclusion.  $H_2$  has 0.74 and a negative sign, while  $H_5$  obtains probability around 0.40 and a positive (and small) sign of the effect on growth.

Finally, both sectoral variables receive probabilities of inclusion above 0.90, and they show opposite signs: GVA agriculture share is positive while GVA industry share is negative.

## 6. CONCLUSIONS

Some conclusions can be drawn from the analysis conducted in this study. Bayesian Model Averaging techniques allow us to determine what variables are strongly related to the growth rate of Spanish provinces. Furthermore, they deal with the problem of model uncertainty, which is one of the main problems of empirical growth regressions. We do not restrict ourselves to check robustness with a fixed set of regressors as in other approaches: we allow for all possible combinations of regressors in a wide set of variables, which include, among others, different types of private, human and public capital.

We find that a number of economic variables have significant correlation with long run growth rates. Among these variables, we can find some types of private and public investment, and some human capital proxies. Moreover, we have found also some variables that should not be taken into account when estimating growth regressions.

The long run results for cross-section supports the conditional (to a set of variables) convergence hypothesis: the initial level of per capita income has high posterior probability of inclusions and has a negative estimated sign.

As expected, private capital plays an important role in determining provincial growth rates. Moreover, private investment in industry and construction seem to be the two types of private investment with highest probability of inclusion in a growth equation. Human capital results are less clear. In the panel data framework, it seems to be an important growth determinant: the share of working age population with studies up to primary school seems to have a negative effect on growth.

Public investment is significantly correlated with growth when using panel data techniques: with a positive elasticity of around 1%. Public investment in roads and highways is the only type of public investment with a high posterior probability of inclusion and a positive coefficient (0.5%). The other types of public investment showed low probability of inclusion or very small and often negative estimated parameters.

The sectoral structure of the economy seems to have an effect on the growth rate of the economy, both the GVA agriculture and industry share have high probabilities of inclusion using panel data techniques (lower when we introduced them in a cross-section regression). The signs are positive for the provincial agriculture share, and negative for the industry share on GVA.

Finally, some cautions should be raised when interpreting the results. The empirical literature on growth regressions has pointed out some econometric problems of classical growth regressions (either cross-section and panel data approaches), and different econometric techniques have been applied to overcome these problems (for instance, instrumental variables or cointegration techniques). However, the analysis here presented wants to revise model uncertainty and robustness of results in the classical approach, so extensively used. We realise about the problems that the estimation can face in the framework chosen, and we intend, as further research, to include new econometric developments, especially new estimation methods, variables, and data sets, into the Bayesian Model Averaging approach.

## 7. APPENDIX

### 7.1. Testing the Program

In order to test the Gauss code employed in our empirical estimations, the panel data model was estimated with a simulated sample. The sample size was  $N=50$  and  $T=3$ . 20 potential regressors were simulated independently from a standard normal distribution. Only ten of the regressors had a non zero effect on the dependent variable. The time variant error term was simulated from independent standard normal distributions. The true values for all individual effects were zero.

Table A shows the true value of the parameters, the Bayesian probability of inclusion, and the posterior mean. For the sake of comparison, we also include the results of a classical fixed effects estimator, which include all potential regressors.

From the results in the table, the probability of inclusion is one when the absolute value of the parameter is larger than 0.5, and it is small otherwise. The error in estimating each parameter is not always smaller with the Bayesian methodology. However, the mean squared error in estimating all parameters is smaller with the Bayesian methodology (0.00885 versus 0.01344).

## **NORMAS DE PUBLICACIÓN DE PAPELES DE TRABAJO DEL INSTITUTO DE ESTUDIOS FISCALES**

Esta colección de *Papeles de Trabajo* tiene como objetivo ofrecer un vehículo de expresión a todas aquellas personas interesadas en los temas de Economía Pública. Las normas para la presentación y selección de originales son las siguientes:

1. Todos los originales que se presenten estarán sometidos a evaluación y podrán ser directamente aceptados para su publicación, aceptados sujetos a revisión, o rechazados.
2. Los trabajos deberán enviarse por duplicado a la Subdirección de Estudios Tributarios. Instituto de Estudios Fiscales. Avda. Cardenal Herrera Oria, 378. 28035 Madrid.
3. La extensión máxima de texto escrito, incluidos apéndices y referencias bibliográficas será de 7000 palabras.
4. Los originales deberán presentarse mecanografiados a doble espacio. En la primera página deberá aparecer el título del trabajo, el nombre del autor(es) y la institución a la que pertenece, así como su dirección postal y electrónica. Además, en la primera página aparecerá también un abstract de no más de 125 palabras, los códigos JEL y las palabras clave.
5. Los epígrafes irán numerados secuencialmente siguiendo la numeración arábiga. Las notas al texto irán numeradas correlativamente y aparecerán al pie de la correspondiente página. Las fórmulas matemáticas se numerarán secuencialmente ajustadas al margen derecho de las mismas. La bibliografía aparecerá al final del trabajo, bajo la inscripción "Referencias" por orden alfabético de autores y, en cada una, ajustándose al siguiente orden: autor(es), año de publicación (distinguiendo a, b, c si hay varias correspondientes al mismo autor(es) y año), título del artículo o libro, título de la revista en cursiva, número de la revista y páginas.
6. En caso de que aparezcan tablas y gráficos, éstos podrán incorporarse directamente al texto o, alternativamente, presentarse todos juntos y debidamente numerados al final del trabajo, antes de la bibliografía.
7. En cualquier caso, se deberá adjuntar un disquete con el trabajo en formato word. Siempre que el documento presente tablas y/o gráficos, éstos deberán aparecer en ficheros independientes. Asimismo, en caso de que los gráficos procedan de tablas creadas en excel, estas deberán incorporarse en el disquete debidamente identificadas.

***Junto al original del Papel de Trabajo se entregará también un resumen de un máximo de dos folios que contenga las principales implicaciones de política económica que se deriven de la investigación realizada.***

## **PUBLISHING GUIDELINES OF WORKING PAPERS AT THE INSTITUTE FOR FISCAL STUDIES**

This serie of *Papeles de Trabajo* (working papers) aims to provide those having an interest in Public Economics with a vehicle to publicize their ideas. The rules governing submission and selection of papers are the following:

1. The manuscripts submitted will all be assessed and may be directly accepted for publication, accepted with subjections for revision or rejected.
2. The papers shall be sent in duplicate to Subdirección General de Estudios Tributarios (The Deputy Direction of Tax Studies), Instituto de Estudios Fiscales (Institute for Fiscal Studies), Avenida del Cardenal Herrera Oria, nº 378, Madrid 28035.
3. The maximum length of the text including appendices and bibliography will be no more than 7000 words.
4. The originals should be double spaced. The first page of the manuscript should contain the following information: (1) the title; (2) the name and the institutional affiliation of the author(s); (3) an abstract of no more than 125 words; (4) JEL codes and keywords; (5) the postal and e-mail address of the corresponding author.
5. Sections will be numbered in sequence with arabic numerals. Footnotes will be numbered correlatively and will appear at the foot of the corresponding page. Mathematical formulae will be numbered on the right margin of the page in sequence. Bibliographical references will appear at the end of the paper under the heading "References" in alphabetical order of authors. Each reference will have to include in this order the following terms of references: author(s), publishing date (with an a, b or c in case there are several references to the same author(s) and year), title of the article or book, name of the journal in italics, number of the issue and pages.
6. If tables and graphs are necessary, they may be included directly in the text or alternatively presented altogether and duly numbered at the end of the paper, before the bibliography.
7. In any case, a floppy disk will be enclosed in Word format. Whenever the document provides tables and/or graphs, they must be contained in separate files. Furthermore, if graphs are drawn from tables within the Excell package, these must be included in the floppy disk and duly identified.

***Together with the original copy of the working paper a brief two-page summary highlighting the main policy implications derived from the research is also requested.***

## ÚLTIMOS PAPELES DE TRABAJO EDITADOS POR EL INSTITUTO DE ESTUDIOS FISCALES

### 2000

- 1/00 Crédito fiscal a la inversión en el impuesto de sociedades y neutralidad impositiva: Más evidencia para un viejo debate.  
*Autor.* Desiderio Romero Jordán.  
Páginas: 40.
- 2/00 Estudio del consumo familiar de bienes y servicios públicos a partir de la encuesta de presupuestos familiares.  
*Autores:* Ernesto Carrillo y Manuel Tamayo.  
Páginas: 40.
- 3/00 Evidencia empírica de la convergencia real.  
*Autores:* Lorenzo Escot y Miguel Ángel Galindo.  
Páginas: 58.

### *Nueva Época*

- 4/00 The effects of human capital depreciation on experience-earnings profiles: Evidence salaried spanish men.  
*Autores:* M. Arrazola, J. de Hevia, M. Risueño y J. F. Sanz.  
Páginas: 24.
- 5/00 Las ayudas fiscales a la adquisición de inmuebles residenciales en la nueva Ley del IRPF: Un análisis comparado a través del concepto de coste de uso.  
*Autor.* José Félix Sanz Sanz.  
Páginas: 44.
- 6/00 Las medidas fiscales de estímulo del ahorro contenidas en el Real Decreto-Ley 3/2000: análisis de sus efectos a través del tipo marginal efectivo.  
*Autores:* José Manuel González Páramo y Nuria Badenes Plá.  
Páginas: 28.
- 7/00 Análisis de las ganancias de bienestar asociadas a los efectos de la Reforma del IRPF sobre la oferta laboral de la familia española.  
*Autores:* Juan Prieto Rodríguez y Santiago Álvarez García.  
Páginas 32.
- 8/00 Un marco para la discusión de los efectos de la política impositiva sobre los precios y el *stock* de vivienda.  
*Autor.* Miguel Ángel López García.  
Páginas 36.
- 9/00 Descomposición de los efectos redistributivos de la Reforma del IRPF.  
*Autores:* Jorge Onrubia Fernández y María del Carmen Rodado Ruiz.  
Páginas 24.
- 10/00 Aspectos teóricos de la convergencia real, integración y política fiscal.  
*Autores:* Lorenzo Escot y Miguel Ángel Galindo.  
Páginas 28.

## 2001

- 1/01 Notas sobre desagregación temporal de series económicas.  
*Autor:* Enrique M. Quilis.  
Páginas 38.
- 2/01 Estimación y comparación de tasas de rendimiento de la educación en España.  
*Autores:* M. Arrazola, J. de Hevia, M. Risueño y J. F. Sanz.  
Páginas 28.
- 3/01 Doble imposición, "efecto clientela" y aversión al riesgo.  
*Autores:* Antonio Bustos Gisbert y Francisco Pedraja Chaparro.  
Páginas 34.
- 4/01 Non-Institutional Federalism in Spain.  
*Autor:* Joan Rosselló Villalonga.  
Páginas 32.
- 5/01 Estimating utilisation of Health care: A group data regression approach.  
*Autora:* Mabel Amaya Amaya.  
Páginas 30.
- 6/01 Shapley inequality decomposition by factor components.  
*Autores:* Mercedes Sastre y Alain Trannoy.  
Páginas 40.
- 7/01 An empirical analysis of the demand for physician services across the European Union.  
*Autores:* Sergi Jiménez Martín, José M. Labeaga y Maite Martínez-Granado.  
Páginas 40.
- 8/01 Demand, childbirth and the costs of babies: evidence from Spanish panel data.  
*Autores:* José M.ª Labeaga, Ian Preston y Juan A. Sanchis-Llopis.  
Páginas 56.
- 9/01 Imposición marginal efectiva sobre el factor trabajo: Breve nota metodológica y comparación internacional.  
*Autores:* Desiderio Romero Jordán y José Félix Sanz Sanz.  
Páginas 40.
- 10/01 A non-parametric decomposition of redistribution into vertical and horizontal components.  
*Autores:* Irene Perrote, Juan Gabriel Rodríguez y Rafael Salas.  
Páginas 28.
- 11/01 Efectos sobre la renta disponible y el bienestar de la deducción por rentas ganadas en el IRPF.  
*Autora:* Nuria Badenes Plá.  
Páginas 28.
- 12/01 Seguros sanitarios y gasto público en España. Un modelo de microsimulación para las políticas de gastos fiscales en sanidad.  
*Autor:* Ángel López Nicolás.  
Páginas 40.
- 13/01 A complete parametrical class of redistribution and progressivity measures.  
*Autores:* Isabel Rabadán y Rafael Salas.  
Páginas 20.
- 14/01 La medición de la desigualdad económica.  
*Autor:* Rafael Salas.  
Páginas 40.

- 15/01 Crecimiento económico y dinámica de distribución de la renta en las regiones de la UE: un análisis no paramétrico.  
*Autores:* Julián Ramajo Hernández y María del Mar Salinas Jiménez.  
Páginas 32.
- 16/01 La descentralización territorial de las prestaciones asistenciales: efectos sobre la igualdad.  
*Autores:* Luis Ayala Cañón, Rosa Martínez López y Jesus Ruiz-Huerta.  
Páginas 48.
- 17/01 Redistribution and labour supply.  
*Autores:* Jorge Onrubia, Rafael Salas y José Félix Sanz.  
Páginas 24.
- 18/01 Medición de la eficiencia técnica en la economía española: El papel de las infraestructuras productivas.  
*Autoras:* M.ª Jesús Delgado Rodríguez e Inmaculada Álvarez Ayuso.  
Páginas 32.
- 19/01 Inversión pública eficiente e impuestos distorsionantes en un contexto de equilibrio general.  
*Autores:* José Manuel González-Páramo y Diego Martínez López.  
Páginas 28.
- 20/01 La incidencia distributiva del gasto público social. Análisis general y tratamiento específico de la incidencia distributiva entre grupos sociales y entre grupos de edad.  
*Autor:* Jorge Calero Martínez.  
Páginas 36.
- 21/01 Crisis cambiarias: Teoría y evidencia.  
*Autor:* Óscar Bajo Rubio.  
Páginas 32.
- 22/01 Distributive impact and evaluation of devolution proposals in Japanese local public finance.  
*Autores:* Kazuyuki Nakamura, Minoru Kunizaki y Masanori Tahira.  
Páginas 36.
- 23/01 El funcionamiento de los sistemas de garantía en el modelo de financiación autonómica.  
*Autor:* Alfonso Utrilla de la Hoz.  
Páginas 48.
- 24/01 Rendimiento de la educación en España: Nueva evidencia de las diferencias entre Hombres y Mujeres.  
*Autores:* M. Arrazola y J. de Hevia.  
Páginas 36.
- 25/01 Fecundidad y beneficios fiscales y sociales por descendientes.  
*Autora:* Anabel Zárate Marco.  
Páginas 52.
- 26/01 Estimación de precios sombra a partir del análisis Input-Output: Aplicación a la economía española.  
*Autora:* Guadalupe Souto Nieves.  
Páginas 56.
- 27/01 Análisis empírico de la depreciación del capital humano para el caso de las Mujeres y los Hombres en España.  
*Autores:* M. Arrazola y J. de Hevia.  
Páginas 28.

- 28/01 Equivalence scales in tax and transfer policies.  
*Autores:* Luis Ayala, Rosa Martínez y Jesús Ruiz-Huerta.  
Páginas 44.
- 29/01 Un modelo de crecimiento con restricciones de demanda: el gasto público como amortiguador del desequilibrio externo.  
*Autora:* Belén Fernández Castro.  
Páginas 44.
- 30/01 A bi-stochastic nonparametric estimator.  
*Autores:* Juan G. Rodríguez y Rafael Salas.  
Páginas 24.

## 2002

- 1/02 Las cestas autonómicas.  
*Autores:* Alejandro Esteller, Jorge Navas y Pilar Sorribas.  
Páginas 72.
- 2/02 Evolución del endeudamiento autonómico entre 1985 y 1997: la incidencia de los Escenarios de Consolidación Presupuestaria y de los límites de la LOFCA.  
*Autores:* Julio López Laborda y Jaime Vallés Giménez.  
Páginas 60.
- 3/02 Optimal Pricing and Grant Policies for Museums.  
*Autores:* Juan Prieto Rodríguez y Víctor Fernández Blanco.  
Páginas 28.
- 4/02 El mercado financiero y el racionamiento del endeudamiento autonómico.  
*Autores:* Nuria Alcalde Fradejas y Jaime Vallés Giménez.  
Páginas 36.
- 5/02 Experimentos secuenciales en la gestión de los recursos comunes.  
*Autores:* Lluís Bru, Susana Cabrera, C. Mónica Capra y Rosario Gómez.  
Páginas 32.
- 6/02 La eficiencia de la universidad medida a través de la función de distancia: Un análisis de las relaciones entre la docencia y la investigación.  
*Autores:* Alfredo Moreno Sáez y David Trillo del Pozo.  
Páginas 40.
- 7/02 Movilidad social y desigualdad económica.  
*Autores:* Juan Prieto-Rodríguez, Rafael Salas y Santiago Álvarez-García.  
Páginas 32.
- 8/02 Modelos BVAR: Especificación, estimación e inferencia.  
*Autor:* Enrique M. Quilis.  
Páginas 44.
- 9/02 Imposición lineal sobre la renta y equivalencia distributiva: Un ejercicio de microsimulación.  
*Autores:* Juan Manuel Castañer Carrasco y José Félix Sanz Sanz.  
Páginas 44.
- 10/02 The evolution of income inequality in the European Union during the period 1993-1996.  
*Autores:* Santiago Álvarez García, Juan Prieto-Rodríguez y Rafael Salas.  
Páginas 36.

- 11/02 Una descomposición de la redistribución en sus componentes vertical y horizontal:  
Una aplicación al IRPF.  
*Autora:* Irene Perrote.  
Páginas 32.
- 12/02 Análisis de las políticas públicas de fomento de la innovación tecnológica en las regiones españolas.  
*Autor:* Antonio Fonfría Mesa.  
Páginas 40.
- 13/02 Los efectos de la política fiscal sobre el consumo privado: nueva evidencia para el caso español.  
*Autores:* Agustín García y Julián Ramajo.  
Páginas 52.
- 14/02 Micro-modelling of retirement behavior in Spain.  
*Autores:* Michele Boldrin, Sergi Jiménez-Martín y Franco Peracchi.  
Páginas .
- 15/02 Estado de salud y participación laboral de las personas mayores.  
*Autores:* Juan Prieto Rodríguez, Desiderio Romero Jordán y Santiago Álvarez García.  
Páginas 40.
- 16/02 Technological change, efficiency gains and capital accumulation in labour productivity growth and convergence: an application to the Spanish regions.  
*Autora:* M.ª del Mar Salinas Jiménez.  
Páginas 40.
- 17/02 Déficit público, masa monetaria e inflación. Evidencia empírica en la Unión Europea.  
*Autor:* César Pérez López.  
Páginas 40.
- 18/02 Tax evasion and relative contribution.  
*Autora:* Judith Panadés i Martí.  
Páginas 28.
- 19/02 Fiscal policy and growth revisited: the case of the Spanish regions.  
*Autores:* Oscar Bajo Rubio, Camen Díaz Roldán y M. Dolores Montávez Garcés.  
Páginas 28.
- 20/02 Optimal endowments of public investment: an empirical analysis for the Spanish regions.  
*Autores:* Oscar Bajo Rubio, Camen Díaz Roldán y M.ª Dolores Montávez Garcés.  
Páginas 28.
- 21/02 Régimen fiscal de la previsión social empresarial. Incentivos existentes y equidad del sistema.  
*Autor:* Félix Domínguez Barrero.  
Páginas 52.
- 22/02 Poverty statics and dynamics: does the accounting period matter?.  
*Autores:* Olga Cantó, Coral del Río y Carlos Gradín.  
Páginas 52.
- 23/02 Public employment and redistribution in Spain.  
*Autores:* José Manuel Marqués Sevillano y Joan Rosselló Villallonga.  
Páginas 36.

- 24/02 La evolución de la pobreza estática y dinámica en España en el periodo 1985-1995.  
*Autores:* Olga Cantó, Coral del Río y Carlos Gradín.  
 Páginas: 76.
- 25/02 Estimación de los efectos de un "tratamiento": una aplicación a la Educación superior en España.  
*Autores:* M. Arrazola y J. de Hevia.
